I worked through all three coding tasks and the knowledge check questions for this lab, including fixing a bug in the starter code where model.fit(X_train, y_train) failed due to missing values in the 'Age' column. When the initial ValueError popped up, I used AI as a quick troubleshooting reference to see why Python 3.14.7 rejected the df['Age'].fillna(..., inplace=True) line and to double-check the sklearn parameters. Once I updated the code to use direct assignment (df['Age'] = df['Age'].fillna(df['Age'].median())), I ran the cells to generate the confusion matrix heatmap, the classification report, and the 5-fold cross-validation scores, and wrote out the scenario comparisons in my own words.
